FOREWORD

The work described in this report was performed between January 1971 and January 1972 as a part of Project 2567 in support of munition development programs such as the Close Air Support Weapon and the Modular Weapon Series at the Air Force Armament Laboratory, Eglin Air Force Base, Florida.

This technical report has been reviewed and is approved.

RANDALL L. FETTY, Colonel, USAF
Chief, Product Assurance Division

ABSTRACT

A computer program using an iterative technique was developed for determining the radius of action of F-4E and A-7D aircraft with any configuration of external stores. The program uses performance data from the aircraft flight manuals to calculate fuel and distance required to achieve military power climbs and optimum cruise fuel consumption. Required inputs to the program include the initial amount of fuel onboard and aircraft gross weight, the cruise and loiter altitudes, and the outbound and returning drag indicies due to aerodynamic drag of the external stores. Optional inputs that provide increased accuracy include fuel for engine start and taxi, and fuel and distance for takeoff and descent. The program calculates sequential increments of the outbound cruise portion of the mission profile until the fuel reserve desired at the end of mission (return to home base) is obtained; thus the radius of action is determined.

Distribution limited to U. S. Government agencies only;
this report documents test and evaluation; distribution
limitation applied January 1973. Other requests for this
document must be referred to the Air Force Armament
Laboratory (DLGC), Eglin Air Force Base, Florida 32542.

SECTION I

INTRODUCTION

Carriage of external stores (weapons, fuel tanks, instrumentation packages, and suspension equipment) can result in large degradations to the range and speed performance of tactical fighter aircraft such as the F-4E and A-7D. Some weapon configurations exhibit aerodynamic drag characteristics that are as great as those of the aircraft itself; consequently, the aircraft range performance may be reduced as much as 50 percent. Therefore degradation plays a significant role in overall mission effectiveness, and the store developer must consider aerodynamic drag as an important parameter in the many trade-offs leading to the final design. This report describes a computer program developed for evaluating range performance effectiveness. The program can readily be used on a parametric basis and will provide a quantitative method of assessing the effect of aerodynamic drag on the aircraft combat radius of action.

The validity of the program results depends primarily on the accuracy of the store drag input data. Both the F-4E and A-7D aircraft utilize a drag index system based on the increment of aerodynamic drag due to external stores. Each external store authorized for carriage has a drag index assigned which included interference effects resulting from the additional drag of stores in close proximity to one another. The total drag index of a particular configuration is obtained by summing the individual drag indicies of the external stores as described in the appropriate aircraft flight manuals (e.g., References 1 and 2). Precise drag indicies cannot be determined without extensive wind tunnel tests and/or flight testing; however, good approximations for an untested store can be obtained from wind tunnel data of similar stores. References 3 and 4 describe techniques for the latter procedure, and methods for reducing wind tunnel data to obtain more accurate drag indicies may be found in Reference 5. A typical mission profile is shown in Figure 1. Performance data from the F-4E and A-7D aircraft flight manuals (References 1 and 2) are used to calculate the fuel and distance required for military power climbs and optimum cruise fuel consumption rates. Inputs to the program are the initial fuel weight and aircraft gross weight, the cruise and loiter altitudes, and the outbound and returning drag indicies of the external stores. The amount of fuel required for engine start, taxi, takeoff, and descent, as well as the distance required for takeoff and for descent, are optional inputs that can provide increased accuracy. The program calculates sequential increments of the outbound cruise portion of the mission profile until the fuel reserve desired after returning to base is obtained; thus determining the radius of action. The program can be used for any mission profile provided that the cruise portion is conducted at the optimum condition for the altitude selected and that a military power climb to altitude is assumed.

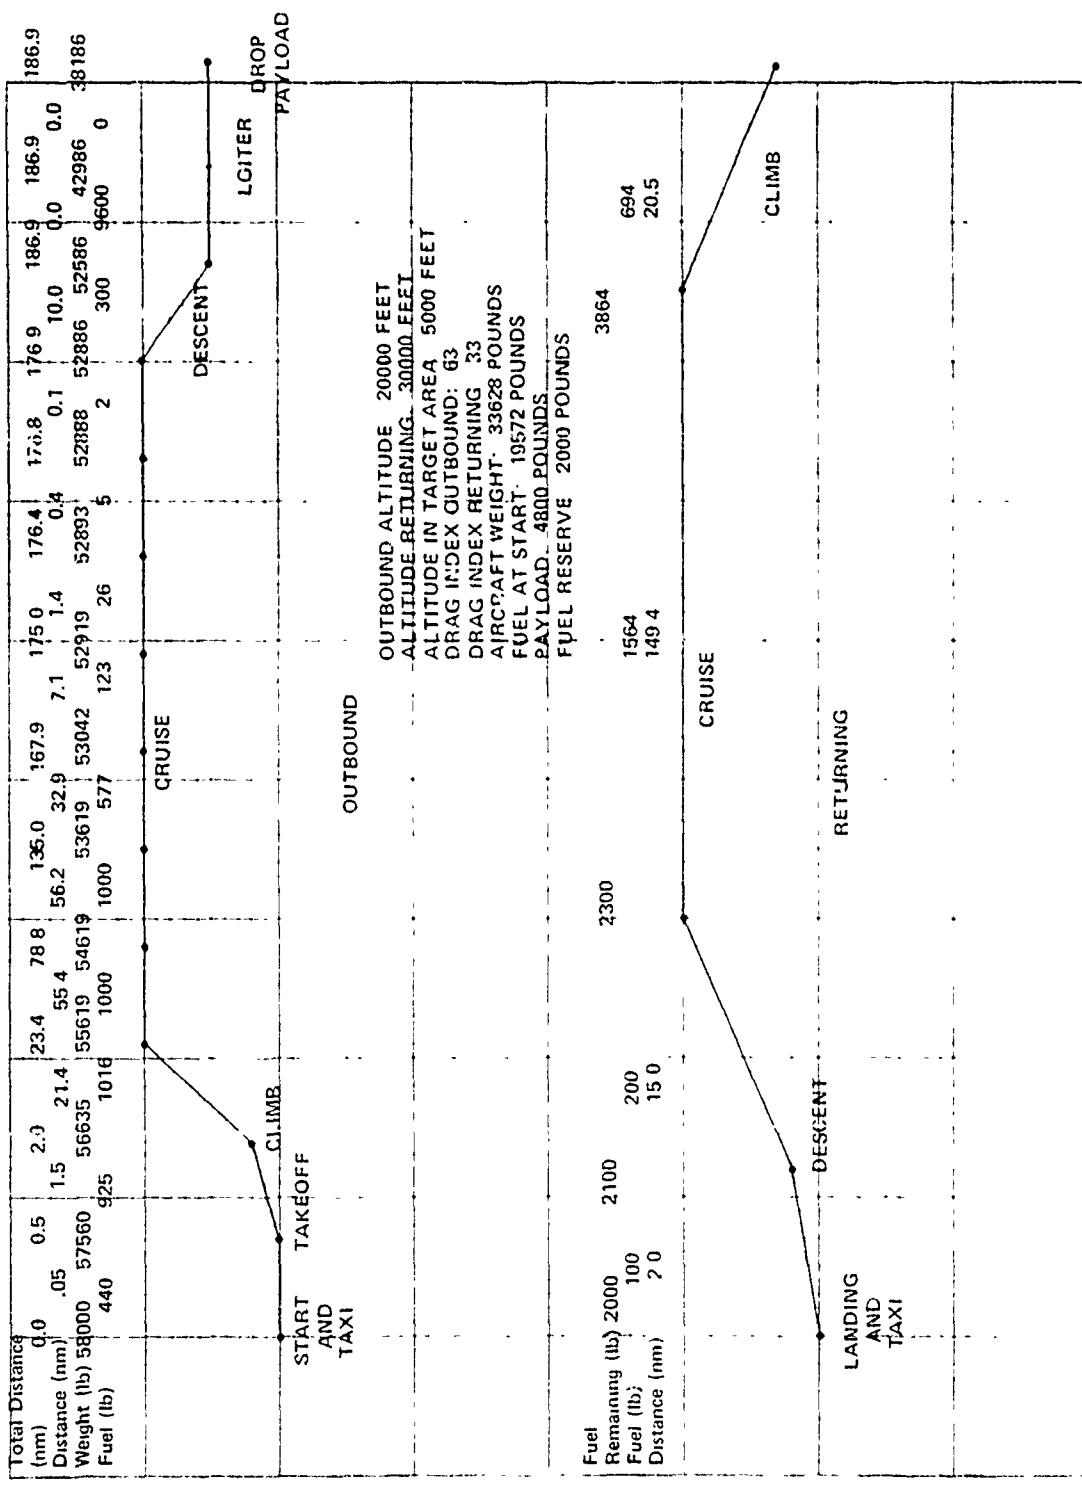

Figure 1. Final Iteration for a Typical High-Low-High Tactical Fighter Mission

SECTION II

DEVELOPMENT OF THE ITERATIVE TECHNIQUE

The fuel and distance required for the climb and cruise portions of the mission are highly dependent upon the outbound and returning altitudes and drag indices; however, the fuel and distance for engine start, taxi, and takeoff are independent of these parameters. Also, a good approximation for descent from any altitude for any drag index is that the fuel expended and the distance traveled are both zero. Therefore, for parametric studies, engine start, taxi, takeoff, and descent can be considered as constants. Guide lines for obtaining accurate estimates for these portions of the mission are contained in the aircraft flight manuals. The program is designed to accept the following estimates as input data:

- a. Fuel and distance traveled away from home base for start and taxi.
- b. Fuel and distance traveled away from home base for takeoff.
- c. Fuel and distance traveled away from home base for outbound descent.
- d. Fuel and distance traveled away from target for descent returning.
- e. Fuel and distance traveled away from home base during loiter in target area.

Additional required program inputs are as follows:

- a. Aircraft type.
- b. Altitude outbound in the target area, and returning.
- c. Fuel at engine start.
- d. Payload (any weight which might be dropped, ejected, or jettisoned during mission).
- e. Basic aircraft weight (gross weight minus fuel and payload).
- f. Fuel reserve at end of mission.
- g. Payload not dropped, ejected, or jettisoned during mission.
- h. Drag index outbound and returning.

The drag indices outbound and returning from the target area should be determined by the best available means.

For each set of input data, radii of action are determined for loiter fuels of 9600 pounds down to 0 in increments of 1200 pounds. Obviously, the amount of fuel available for loiter can be used to approximate a permissible loiter time.

If the altitude in the target area is greater than zero but less than 5000 feet, the program automatically changes to either zero or 5000 feet based upon the magnitude of the input value. This conversion is necessary because the subroutines are unable to determine accurate values for this range of altitudes.

Further, if the aircraft gross weight at engine start exceeds that allowable for the aircraft, fuel is downloaded automatically in the program to the point where the gross weight is within allowable limits.

The weight and distance traveled away from home base is determined by subtracting all fuel used and adding all distances traveled. Subroutines are then called which provide the fuel and distance required to climb to the outbound altitude; at that time new weight and distance values are determined and retained. If this is followed by a cruise, it will be a 1000-pound-fuel cruise, and the gross weight at the beginning of the cruise will be used. The estimated subsequent fuel requirements determine whether a 1000-pound-fuel cruise is undertaken. Another subroutine provides the fuel consumption rate. After the outbound climb or the 1000-pound-fuel cruise, as the case may be, the outbound descent is made, a 9600-pound-fuel loiter is completed; all, none, or some portion of the payload is dropped; and the return trip home is begun after the distance from home base to the target is noted.

Each of the climb subroutines is called twice to determine the fuel and distance required to proceed from target altitude to the return altitude. The amount required to climb from sea level to the target altitude is subtracted from the amount required to climb from sea level to the return altitude.

After the return climb is completed, the cruise subroutine is called to determine a fuel consumption rate for the beginning of the return cruise. With the fuel data for the return descent and for landing and taxi, the desired gross weight at the end of the return cruise and the fuel consumption rate at this point are known. The same distance data, the return climb distance, and the distance from home base to the target, are used to calculate the return cruise distance. The fuel consumption rates are averaged, and the fuel required for the return cruise is computed.

The trial mission is completed and the extra fuel determined. If the extra fuel is less than minus one pound, the mission can not be completed for the specified loiter fuel, and another simulated mission is attempted with 1200 pounds less fuel for loiter. If the extra fuel amounts to one pound or more, either one-half, one-third, or 1000 pounds of it are used for a cruise or an additional outbound cruise to the target area. The appropriate quantity to be used is determined by the relation of the outbound and returning drag indices combined with the amount of extra fuel. The iteration is repeated using either the weight and distance after the outbound climb or the weight and distance after the last outbound cruise, if one has occurred, until the mission is completed with the desired quantity of extra fuel (zero or minus one pound). Thus, the radius of action has been determined.

Subsequent radii are determined for loiter fuels incremented by minus 1200 pounds until the fuel for loiter has been reduced to zero pounds. Instead of simulating the new mission from the very beginning, the new iteration is begun after the outbound climb or the last 1000-pound-fuel cruise, if one has occurred.

Appendices I, II, and III contain the radius-of-action program listing, input list, and limitations, respectively.

SECTION III

DEVELOPMENT OF THE SUBROUTINES

This section discusses the development of the subroutines for calculating the fuel and distance required to climb and the fuel consumption rate, given the aircraft type, altitude, gross weight, and drag index.

The F-4E and A-7D aircraft climb and cruise parameters are displayed in figures contained in the aircraft flight manuals (References 1 and 2). These figures define the fuel consumption rate for optimum cruise, fuel required to climb, and distance required to climb. These figures are set up in a parametric format and are a function of aircraft gross weight, altitude, drag index, and a parametric variable (designated as T in this report). Each figure is divided into two charts with the first chart being a family of curves that are a function of gross weight and altitude which define the dependent variable T. The second chart has a family of curves with independent variables of T and aircraft drag index and with a dependent variable of either fuel for climb, distance for climb, or fuel consumption rate for optimum cruise depending upon which figure is being used. Although no equations define the families of curves, a method was developed to define the families for computer applications. The first chart contains discrete curves which are a function of gross weight, for altitudes of 0, 5000, 1000, . . . , and 40,000 feet. Similarly, the second chart contains discrete curves for drag indices of zero to the maximum in specified increments that are a function of T. The problem then was to find equations of lines for any condition other than those discretely defined. The method used was a Newtonian interpretation technique (Reference 6) that defines an n^{th} order polynomial for n discrete points. The development of the Newtonian equation by this method forces the polynomial to satisfy the n discrete points by definition. The equation then can be used to calculate a value between any of the discrete points.

It was hypothesized that if a family of straight parametric lines was only defined at discrete values, the slope and intercept of any line lying between two defined lines could be determined by interpolation of the defined values. Although the family of curves did not consist of straight lines, the values were approximated by decomposing the curves into a number of straight lines. In the first chart, the curves that are a function of gross weight and altitude are drawn as straight lines between certain gross weights. Similarly in the second chart, the curves that are a function of T and drag index are drawn as straight lines between certain values of T. Now using the Newtonian method, two equations are defined to give the slope and intercept for any altitude line in the first chart. Similarly, two equations are defined that provide the slope and intercept for any drag index line in the second chart. Thus, when the altitude is defined, a linear equation which has gross weight as the independent variable and T as the dependent variable, is constructed with a calculated slope and intercept. When a drag index is defined, another linear equation, which has T as the independent variable and either fuel for climb, distance for climb, or fuel for cruise as the dependent variable, is constructed with a calculated slope and intercept.

Three computer subroutines were constructed to incorporate the method just described. One subroutine will construct the equations for determining the fuel for climb, a second subroutine will give the equation for distance to climb, and a third subroutine is concerned with the fuel consumption rate for optimum cruise.

Appendices IV and V contain the main programs and two additional subroutines for utilizing the three radius-of-action subroutines to obtain tabular data for the following independent variables:

a. F-4E (see Appendix VI)

- (1) Altitude (5000 to 40000 feet in increments of 2500 feet).
- (2) Weight (30000 to 58000 pounds in increments of 1000 pounds).
- (3) Drag index (0 to 140 in increments of 10).

b. A-7D

- (1) Altitude (5000 to 40000 feet in increments of 2500 feet).
- (2) Weight (20000 to 42000 pounds in increments of 1000 pounds).
- (3) Drag index (0 to 300 in increments of 20).

SECTION IV

APPLICATION OF THE TECHNIQUE

As an example, assume that the radius of action for an F-4E aircraft is to be determined for a high-low-high mission at altitudes of 20000 feet outbound, 5000 feet in the target area (loiter), and 30,000 feet returning. Further, assume some realistic values for the mission segments (Figure 1) as follows:

	Fuel, lb	Distance, N. M.
Start and Taxi	440	0.5
Takeoff	925	1.5
Descent going to target	300	10.0
Descent returning from target	200	15.0
Landing and taxi	100	2.0
Loiter	N/A	0.0

Also, assume that the payload is six 800-pound weapons; all of which are to be dropped from the triple ejector rack on the inboard armament stations. A typical fuel reserve at the end of a mission is 2000 pounds.

The aircraft incremental drag as a result of weapon carriage (weapon drag index) is largely dependent upon weapon shape and diameter and can conceivably vary from a total weapon drag index of 30 to 60. Figure 2 shows the radius of action as a function of loiter fuel for two weapon drag indicies and three fuel loadings. Note that when fuel was carried on the centerline and outboard stations with the large payload, 1198 pounds had to be downloaded so as not to exceed the maximum gross weight of 58000 pounds. This makes the increase in the radius of action based on outboard and centerline fuel somewhat less than if the payload was less.

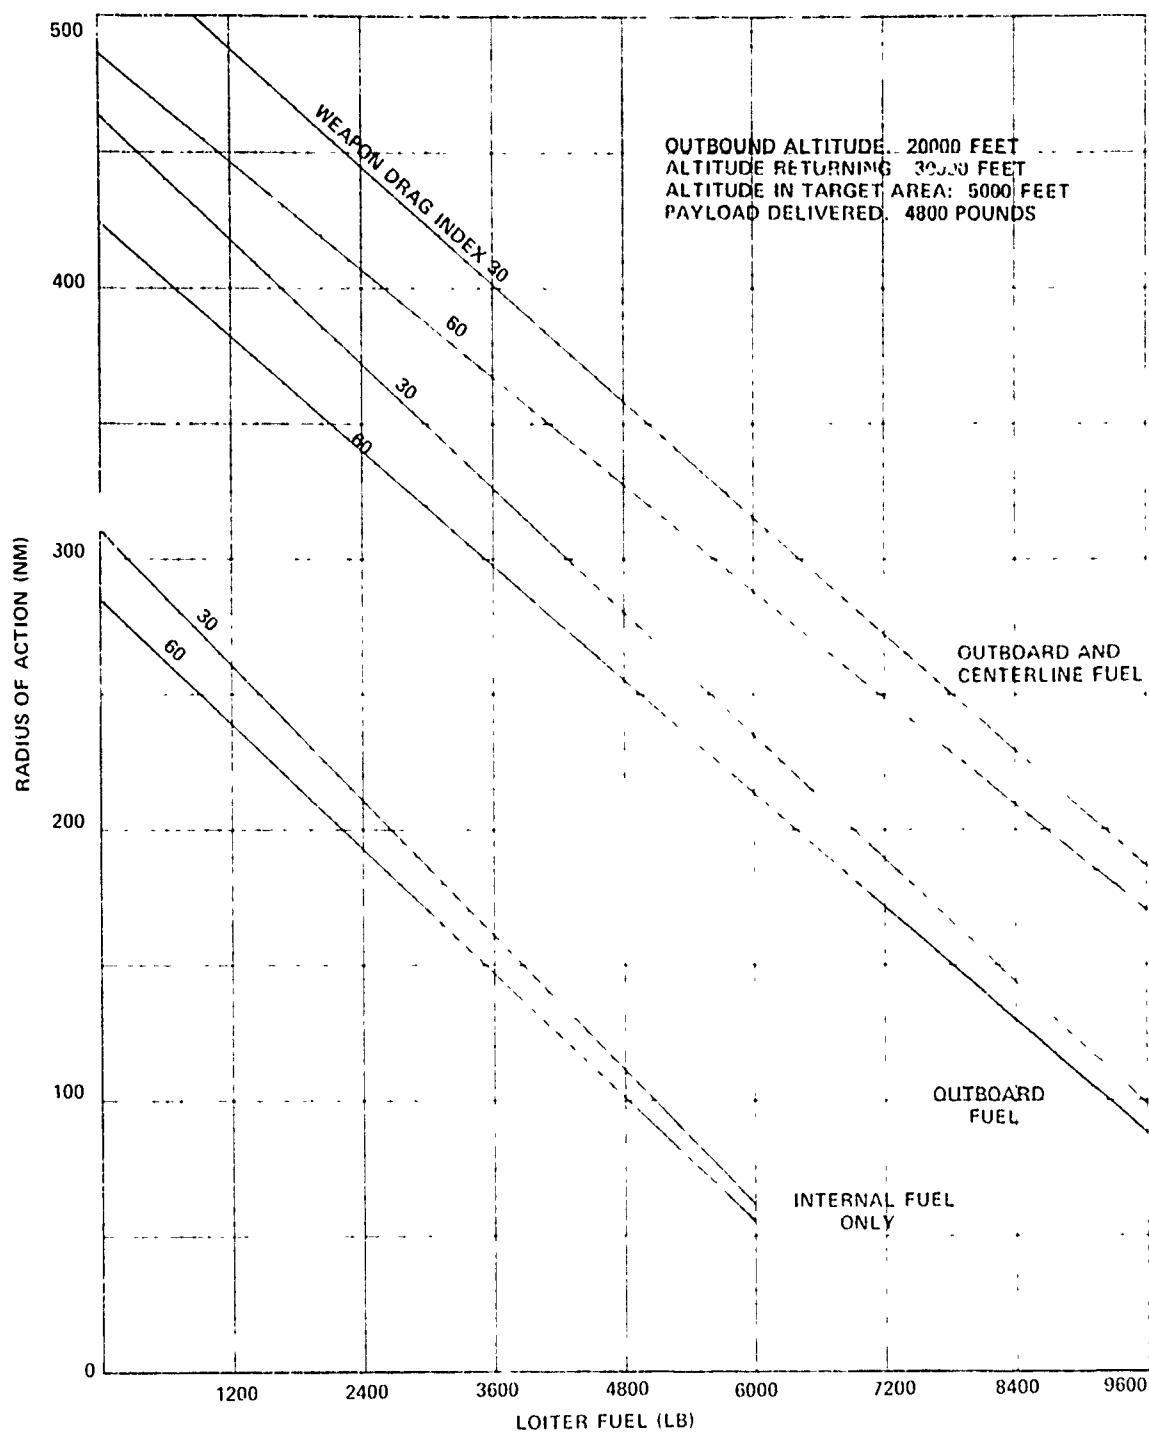

Figure 2. Radius of Action Versus Loiter Fuel for Two Weapon Drag Indices and Three Fuel Loadings

(The reverse of this page is blank)

INPUT LIST

COLUMN	VARIABLE	FORMAT	
TYPE ONE CARD:			
1-10	ACFT	A	Aircraft: Left-hand justify
11-15	ALTG	F	Outbound altitude: feet
16-20	ALTR	F	Altitude returning: feet
21-25	ALTAT	F	Altitude in target area: feet
30	C	I	If C equals one, values of parameters are printed out after each segment of the mission for each iteration to permit checkout of the program.
TYPE TWO CARDS:			
1-4	FFSAT	I	Fuel for start and taxi: pounds
5-8	FFTO	I	Fuel for takeoff: pounds
9-12	FFDG	I	Fuel for outbound descent: pounds
17-20	FFDG	I	Fuel for descent returning: pounds
21-24	FFLAT	I	Fuel for landing and taxi: pounds
25-28	FTBR	I	Fuel to be returned: pounds
29-32	PR	I	Payload returned: pounds
33-35	DIG	F	Drag index outbound
36-38	DIR	F	Drag index returning
41-45	FAS	I	Fuel at engine start: pounds
46-50	P	I	Payload (any item capable of being dropped, ejected or jettisoned): pounds
51-56	BAW	I	Basic aircraft weight (gross weight at engine start less fuel and payload): pounds
57-60	DFSAT	F	Distance for start and taxi: NM

COLUMN	VARIABLE	FORMAT	
61-64	DFTO	F	Distance for takeoff: NM
65-68	DFDG	F	Distance for outbound descent: NM
69-72	DFL	F	Distance during loiter in target area: NM
73-76	DFDR	F	Distance for descent returning: NM
77-80	DFLAT	F	Distance for landing and taxi: NM

TYPE THREE CARD - An EOR (7/8/9) card follows the last Type Two card of a set of data
 Any number of sets of data may be used.

APPENDIX III
PROGRAM LIMITATIONS

35
(The reverse of this page is blank)

PROGRAM LIMITATIONS

F-4E and A-7D Aircraft

All climbs are at military thrust.

All cruises are at optimum Mach numbers.

Outbound and returning altitudes: 5,000 to 40,000 feet

Altitude in target area: 0 or 5,000 to 40,000 feet

F-4E restrictions:

Gross weight: 30,000 to 58,000 pounds

Drag indices: 0 to 140

A-7D restrictions:

Gross weight: 20,000 to 42,000 pounds

Drag indices: 0 to 300

13. ABSTRACT <p>A computer program using an iterative technique was developed for determining the radius of action of F-4E and A-7D aircraft with any configuration of external stores. The program uses performance data from the aircraft flight manuals to calculate fuel and distance required to achieve military power climbs and optimum cruise fuel consumption. Required inputs to the program include the initial amount of fuel onboard and aircraft gross weight, the cruise and loiter altitudes, and the outbound and returning drag indices due to aerodynamic drag of the external stores. Optional inputs that provide increased accuracy include fuel for engine start and taxi, and fuel and distance for takeoff and descent. The program calculates sequential increments of the outbound cruise portion of the mission profile until the fuel reserve desired at the end of mission (return to home base) is obtained; thus the radius of action is determined.</p>
